1.2 JWT

1.2.1 JWT 만들기

```python
# -*- coding:utf-8 -*-
from datetime import datetime, timedelta, timezone
from flask import Flask, jsonify, make_response, request
import jwt

secret_key = "abcd"
app = Flask(__name__)

@app.route("/token.get")
def tokenGet():
    name = request.args.get("name")
    price = request.args.get("price")
    payload = {
        "name": name,
        "price": price,
        "exp": datetime.now(timezone.utc) + timedelta(seconds=10),
    }
    token = jwt.encode(payload, secret_key, algorithm="HS256")
    resBody = {"token": token}
    resHeader = {"Access-Control-Allow-Origin": "*"}
    return make_response(jsonify(resBody)), resHeader

if __name__ == "__main__":
    app.run("0.0.0.0", port=8888, debug=True)
```

1.2.2 JWT 확인

```python
@app.route("/token.check")
def tokenCheck():
    try:
        token = request.args.get("token")
        payload = jwt.decode(token, secret_key, algorithms="HS256")
        print(payload["name"])
        print(payload["price"])
        resBody = {"result": "ok"}
    except jwt.ExpiredSignatureError:
        resBody = {"result": "expired"}
    except jwt.exceptions.DecodeError:
        resBody = {"result": "none"}
    return make_response(jsonify(resBody))
```

1.2.3 JWT 갱신

```python
@app.route("/token.update")
def tokenUpdate():
    try:
        token = request.args.get("token")
        payload = jwt.decode(token, secret_key, algorithms="HS256")
        payload = {
            "name": payload["name"],
            "price": payload["price"],
            "exp": datetime.now(timezone.utc) + timedelta(seconds=10),
        }
        token = jwt.encode(payload, secret_key, algorithm="HS256")
        resBody = {"token": token}
    except jwt.ExpiredSignatureError:
        resBody = {"result": "expired"}
    except jwt.exceptions.DecodeError:
        resBody = {"result": "none"}
    resHeader = {"Access-Control-Allow-Origin": "*"}
    return make_response(jsonify(resBody)), resHeader
```
